ANEJO 4: HIDROGEOLOGÍA

1. Objeto y alcance del documento	3
---	---

1. Objeto y alcance del documento

En el presente Anejo se incorpora la información hidrogeológica existente acerca de la zona 4 de los apilamientos de fosfoyesos.

Huelva, Junio de 2022

AVANCE

ESTUDIO HIDROGEOLÓGICO DE LA ZONA 4 DE LAS BALSAS DE FOSFOYESO SITUADAS EN EL TÉRMINO MUNICIPAL DE HUELVA

JUNIO 2022

Propiedad: Fertiberia S.A.

Anejo 1. Datos de los ensayos de bombeo SH-2 y SH-5

1. Objetivos

Los objetivos de la investigación hidrogeológica que se está llevando a cabo son los siguientes:

- Caracterizar hidrogeológicamente el emplazamiento de la Zona 4 de las balsas de fosfoyesos.
- Establecer el modelo conceptual de funcionamiento hidrogeológico en la zona de vertido de los fosfoyesos y de los otros materiales de relleno presentes, así como de los materiales de marisma sobre los que se asientan.

En la situación actual de los trabajos, y tras la revisión crítica de la información relacionada con la geología y las aguas subterráneas existente hasta el momento, buena parte de la caracterización hidrogeológica y del modelo conceptual de funcionamiento del emplazamiento de la Zona 4 se basa en la extrapolación de la investigación hidrogeológica realizada en la Zona 2 en aquellos aspectos comunes a ambas.

2. Investigación hidrogeológica

Para alcanzar los objetivos propuestos las actividades realizadas han sido las siguientes:

2.1. Recopilación y análisis crítico de la información existente

La primera actividad ha consistido en la recopilación y análisis crítico de toda la información y documentos de índole hidrogeológica relacionados con el objeto de estudio.

El objetivo de esta actividad es establecer claramente qué datos se consideran válidos y detectar la información que deberá ser cubierta con la realización de la investigación hidrogeológica subsiguiente.

Se ha efectuado la revisión preliminar del documento que constituye el punto de partida de la investigación hidrogeológica que se acometerá: la **Caracterización de las Balsas de Depósito de Fosfoyesos (Zonas 1 y 4)** efectuada por EGMASA para la Dirección General de Prevención y Calidad Ambiental de la Consejería de Medio Ambiente de Andalucía entre los años 2010 y 2012. Esta caracterización se estructuró en 3 informes:

- Informe de inspección preliminar de la calidad de los suelos y aguas subterráneas asociadas (2010)
- Trabajos adicionales de caracterización para el análisis de riesgos (2011)
- Caracterización exploratoria de la calidad de los suelos y las aguas subterráneas asociadas (Ampliación) (2012)

A continuación se expone un resumen del contenido de dichos informes en lo relativo, exclusivamente, a los aspectos hidrogeológicos de la Zona 4 de las balsas de depósito de los fosfoyesos. En dicho resumen se han intercalado los comentarios que ha suscitado el análisis crítico del documento. Para la correcta interpretación del resumen y análisis efectuado se ha señalado con tipo de letra *cursiva* el resumen del contenido del documento original, manteniendo el tipo de letra normal para los comentarios.

Caracterización de las Balsas de Depósito de Fosfoyesos (Zonas 1 y 4) (eqmasa)

A. OBJETIVOS

Los objetivos de la caracterización efectuada fueron los siguientes:

- Evaluación de la calidad de los suelos y rellenos existentes en el área de depósito de fosfoyesos ubicados en la margen derecha del Río Tinto a la altura de la capital de Huelva, concretamente los situados al norte de la marisma de Mendaña (Zona 4).
- Caracterización adicional para el análisis de riesgos.

B. EMPLAZAMIENTO

La Zona 4 está limitada al oeste por la Marisma de Mendaña, el siguiente estero de gran tamaño que existe a continuación de la Marisma del Rincón, y limita al este con la Ribera de la Nicoba, otro estero importante que penetra hacia el norte, entre las localidades de Huelva y San Juan del Puerto. Al norte se sitúa una zona de marisma sin depósito de fosfoyesos y la antigua carretera Huelva-Sevilla.

Figura 2: Zonas a estudiar de los depósitos 1 y 4 de fosfoyesos

Figura 4: Foto aérea de la zona 4

C. MATERIALES DEPOSITADOS

En la Zona 4, además de los fosfoyesos, se ha identificaron diferentes tipos de rellenos antrópicos que se inscriben dentro del Proyecto de Restauración de estas balsas presentado por Fertiberia, y aprobado mediante Resolución de la Consejería de Medio Ambiente de 2 de julio de 1997, en base al cual los fosfoyesos fueron cubiertos por diferentes materiales clasificados como inertes.

Figura 6: Delimitación de los materiales depositados en la Zona 4 junto a los fosfoyesos

1. Fosfoyesos

Los fosfoyesos se originaron en el proceso de fabricación de ácido fosfórico mediante ataque con ácido sulfúrico de la roca fosfórica, fundamentalmente apatito en alguna de sus variedades ($\text{Ca}_5(\text{PO}_4)_3(\text{F}, \text{Cl}, \text{OH})$); y están constituidos fundamentalmente por sulfato cálcico dihidratado. El ácido fosfórico era posteriormente empleado en la fabricación de fertilizantes, mientras que los fosfoyesos eran vehiculados con el agua de proceso por tubería hacia las balsas de decantación.

Los fosfoyesos, normalmente son de color blanco ligeramente gris y a veces amarillento, según los orígenes de la roca fosfórica empleada (Marruecos, Senegal, etc.), y al tener dos moléculas de agua en su estructura, presentan frecuentemente un aspecto muy fluidificado, especialmente cuando se le somete al rozamiento con la batería de perforación.

Los fosfoyesos fueron vertidos por toda la Zona 4, en un espesor que varía entre 5.2 – 13.5 m.

2. Residuos de Construcción y Demolición (RCD) y otras basuras urbanas

Los RCD se localizan fundamentalmente en la Zona 4, en virtud del Convenio de Colaboración suscrito por Fertiberia, Egmasa y el Excmo. Ayuntamiento de Huelva para la ejecución del proyecto de restauración de Fertiberia para esta zona, y particularmente en su mitad sur (Sector I), donde también se encontraron en las columnas perforadas basuras urbanas consistentes fundamentalmente en biomasa, maderas, etc.. Estos RCD, mezclados en ocasiones con basuras, se encuentran en este Sector I de la zona 4 en paquetes de aproximadamente 0,5-9 m de espesor sobre los fosfoyesos, con un espesor medio en torno a 4 m.

En la mitad norte (Sector II) de la Zona 4, también existe una capa de RCD sobre los depósitos de residuos tratados en espesores que oscilan entre 0.5-3 m.

3. Residuos industriales tratados

En la mitad norte (Sector II) de la Zona 4, en virtud del Convenio de Colaboración suscrito por Fertiberia, Egmasa y el Excmo. Ayuntamiento de Huelva para la ejecución del proyecto de restauración de Fertiberia para esta zona, se procedió a la cubrición de las balsas de fosfoyeso con residuos industriales inertizados, en paquetes que alcanzan espesores de 1 a 2.5 m en las zonas estudiadas.

El inertizado es el producto de mezclar residuos industriales de diferente naturaleza (orgánica e inorgánica) con cemento y cal, obteniéndose una masa silicatada donde las sustancias contaminantes deben quedar encapsuladas y aisladas del medio. El inertizado tiene aspecto de arcilla arenosa de color gris, con olor, plástica en condiciones húmedas, y compacta cuando se seca.

D. EVOLUCIÓN HISTÓRICA

La evolución de los vertidos en el Zona 4 se dedujo a partir del análisis de las fotografías aéreas disponibles.

Figura 17: Ortofotografías de 1956

1977

En el año 1977, la Zona 4 se empezó a compartimentar en balsas, aunque no se observaban aún depósitos de fosfoyesos.

1984

Ya existían depósitos de fosfoyeso en su mitad este, limitando con el arroyo de La Nicoba y el Río Tinto, estando aun prácticamente libres de depósitos la zona noroeste conocida posteriormente como CRI-9 y la mitad oeste de la zona centro-sur, donde posteriormente se ubicaría la estación de transferencia de residuos.

Se advertían algunos reboses laterales sucesivos de fosfoyeso en la parte cóncava del meandro de Mendaña, y un par de ellos en la parte norte que linda con el Arroyo de La Nicoba.

1998

Se observaba que el lateral este presenta importantes depósitos de fosfoyeso, advirtiéndose perfectamente la red de tuberías procedentes de la Zona 3, mientras que en el lateral oeste, se distinguían depósitos de materiales sobre los fosfoyesos ya vertidos tanto en el Sector I como en el

Sector II, desde la partes más próximas a la entrada desde Huelva, es decir desde el NE al SW, alcanzando una extensión de aproximadamente unos 500 m desde la entrada.

También se observaba que en la entrada del Sector I ya se había construido la estación de transferencia de RSU.

2002

En el año 2002 se observaba que gran parte del CRI-9 del Sector II ya se había colmatado y restaurado, distinguiéndose aún depósitos en su frente norte, mientras que estos depósitos empezaban a extenderse ahora sobre los fosfoyesos de las balsas del lateral este que lindan con el Arroyo de La Nicoba.

En el Sector I existía ya una zona restaurada en los alrededores y al sur de la estación de transferencia, mientras que se seguían observando depósitos en el resto de las balsas, en menor medida en la balsa situada más al sur, donde aún se advertían los fosfoyesos sin apilamientos encima.

2005

Se observaba que el CRI-9 estaba colmatado en su totalidad y restaurado, mientras que se seguían observando depósitos en el lateral este del Sector II.

Respecto al Sector I, en el sur ya no se apreciaban fosfoyesos a nivel de superficie, observándose que el volumen de rellenos parecía más importante en la zona central.

2007

En el Sector II habían cesado los depósitos, mientras que aún se observaban depósitos en el Sector I, en la zona más distal a la entrada al recinto (lateral este y sur), mientras que en la zona central se había ampliado hacia el este la zona restaurada.

2009

El Sector II permanecía igual, mientras que en el Sector I se había ampliado la zona restaurada al lateral este, quedando únicamente depósitos en la zona convexa del meandro de Mendaña. Se observaban nuevas plantaciones en la zona restaurada más próxima a la estación de transferencia.

El Sector I se iba cubriendo progresivamente, como se ha comentado anteriormente, con tierra vegetal y RCD en diferentes espesores, a medida que se alcanzaba la cota final del vertido de residuos, continuando en el año 2011 el depósito de esos materiales al menos en una zona deprimida, situada al norte de esta área, donde aflora el nivel freático.

La mitad norte de la Zona 4 (Sector II) se iba cubriendo igualmente de RCD a medida que se alcanzaba la cota final del vertido de residuos, aunque en el lateral este que linda con el río Tinto, había varias zonas donde los depósitos se interrumpieron antes de alcanzar la cota final proyectada, constituyendo

áreas de topografía deprimida (p.ej. puntos P56, P61 y P63 de este estudio), en algunas de las cuales (p.ej. áreas de los puntos P56 y P61), la cobertera superficial era incompleta.

En 1998 se depositaron accidentalmente en la zona denominada CRI-9, el producto inertizado de residuos contaminados con ¹³⁷Cs a causa de un incidente en la planta de origen de los residuos.

Figura 27: Norte de la Zona 4: Zona bajo vigilancia radiométrica (CRI 9) y Sector II estudiado.

A raíz de este accidente, ENRESA identificó y evacuó al depósito de El Cabril los residuos depositados con mayor radiactividad, cubriéndose posteriormente el resto de las zonas en 2001 con una capa de arcilla de 1.5 m de espesor, y estableciéndose un programa de vigilancia radiométrico de las aguas subterráneas, los sedimentos y organismos indicadores.

La existencia de este programa de seguimiento radiológico, bajo la supervisión del órgano sustantivo en esta materia, que es el Consejo de Seguridad Nuclear (CSN), motivó que en el estudio analizado no se hubiese abarcado la zona afectada por el depósito de material radiactivo (CRI-9), ni las aguas subterráneas limítrofes con ella.

Figura 29: Delimitación de zonas relativamente homogéneas sobre localización de balsas en la zona 4

E. GEOLOGÍA DEL EMPLAZAMIENTO

Los terrenos objeto del estudio analizado se sitúan en el dominio geológico de la Depresión del Guadalquivir, en la subcuenca del río Tinto, en su margen derecha, y próximo a su desembocadura, dentro de la zona de influencia mareal.

Tras el depósito de un glacis cuaternario sobre la Formación Arcillas de Gibraleón (Margas azules del Andaluciense), se produjo un encajamiento de la red fluvial que origina tres niveles de terrazas en los márgenes del bloque, y el depósito posterior durante el holoceno de un potente paquete de materiales sedimentarios de marisma en las zonas deprimidas de fractura.

A escala local (zonas de balsas de fosfoyesos), los materiales limo-arenosos de las marismas presentarían la secuencia de unidades de techo a muro que se detalla a continuación:

1. Unidad Fangosa Superior (UFS)

Constituye el primero de los tramos de litologías naturales de la zona, correspondientes al relleno holoceno del estuario del río Tinto.

Se trata de limos habitualmente marrones o incluso rojizos en los primeros centímetros (0.5 m aprox. por término medio) del techo del afloramiento, en ocasiones con restos de raíces y vegetación de marisma, que enseguida pasan a un fango de textura mayoritariamente limosa, limoso-franca o limoso-arcillosa, con presencia en algunos niveles de bioclastos (conchas, etc.)

Se interpretó como la secuencia regresiva correspondiente al relleno del estuario, una vez producida la estabilización del nivel del mar, pasando de sedimentos intermareales (fangos grises) a sedimentos de marisma (fangos rojizos bioturbados).

2. Unidad Arenosa Intermedia (UA)

Presenta espesores muy variables de unos puntos a otros, según que coincidan con la ubicación de antiguos caños de marea, etc., que varían entre los 2 y los 14 m.

Se interpretaron como depósitos submareales instalados tras la estabilización del nivel del mar hace 6000 años, con influencia del oleaje y la marea en un sistema relativamente abierto.

En la Zona 4 no se identificó un nivel arenoso continuo (únicamente aparece en 2 sondeos, con espesores de 1 y 3 m), constituyendo los materiales de estuario un único nivel más o menos homogéneo de limos grises que, por convención, se han identificado en su totalidad como UFS, aunque en realidad este formada por las tres unidades descritas para los materiales de estuario en la Zona 1. Por tanto, en la Zona 4 el complejo estuarino presentaría pequeñas diferencias litológicas apenas observables de visu.

3. Unidad Fangosa Inferior (UFI)

Nivel muy parecido al de los fangos superiores, constituido por limos grises, con un mayor contenido arenoso hacia techo, y frecuentes intercalaciones de bioclastos, fundamentalmente hacia muro, en la transición hacia el conglomerado basal infrayacente, transición en la que también puede haber presencia de un pequeño nivel arenoso o con grava.

Se interpretaron como los primeros depósitos submareales transgresivos, con abundantes eventos de alta energía (niveles bioclásticos).

4. Unidad Conglomerática Basal (UCB)

Nivel que presenta, en primer lugar, a techo, gravas isométricas y gravas arenosas mal clasificadas, con cantos cuarcíticos centimétricos, y en frecuentes ocasiones en matriz limosa de color marrón.

A muro de este primer nivel, separados por discordancia erosiva, conglomerados rojizos, con base igualmente erosiva, de cantos cuarcíticos de más de 5 cm, en matriz de arenas gruesas a muy gruesas, y en ocasiones de lutitas rojas.

El espesor de este paquete, detectado en los sondeos más profundos de la investigación, varía entre los 6-14 m, pudiéndose adoptar como espesor medio los 10 m.

El nivel inferior se interpretó como materiales procedentes del desmantelamiento por erosión de la Unidad Continental Conquero (glacis pleistoceno)

El tramo superior de grano algo más fino, correspondería a los primeros depósitos fluviales con retrabajo mareal, en los momentos iniciales de la transgresión holocena.

5. Arcillas de Gibrleón (ARC)

Nivel arcilloso del mioceno superior (Andaluciense), equiparable a las margas azules del Tortoniense, materiales de gran potencia o espesor y continuidad espacial en la cuenca, que constituyen la base impermeable de todos los depósitos mio-pliocenos y cuaternarios permeables de la Depresión del Guadalquivir, y que en la zona de estudio constituyen igualmente la base impermeable de los rellenos holocenos del estuario del Tinto.

Tabla 2-1. Relación de materiales detectados en el subsuelo de la zona de estudio.

Denominación	Litología
Rellenos	Rellenos antrópicos heterogéneos con presencia de residuos urbanos, residuos de construcción y demolición y residuos industriales (fosfoyesos, cenizas procedentes de tostación de piritas)
UFS	Fangos pardo-rojizos con bioturbación Fangos del complejo estuarino superior
UA	Arenas limosas a arenas y limos arenosos de complejo estuarino medio
UFI	Limos del complejo estuarino medio
UCB	Gravas y conglomerados fluviales del pleistoceno superior. Niveles de limos arenosos y fangos arenosos con gravas del complejo estuarino inferior
Arcillas de Gibraleón	Margas azules del andaluciense

Figura 52: Ubicación de los puntos de muestreo adoptados para investigación exploratoria en suelos. Zona 4

Las perforaciones se efectuaron por sondeo mecánico a rotación con recuperación de testigo en continuo, empleando para ello corona widia de 86/101 mm de diámetro según los casos, y revestimiento posterior de 98/113 mm para la instalación de piezómetro en todos los sondeos.

La investigación se planteó para reconocer tres niveles en profundidad:

- En los pozos de la red de control de los rellenos, la perforación atravesó el espesor completo de rellenos antrópicos, continuando 1.5-2 m más en la marisma para el estudio de la calidad de los suelos infrayacentes.
- En los pozos de la red de control del complejo estuarino superior y medio (UFS, UA y UFI), se perforó al menos unos 3-4 m en los materiales de marisma. Esto supone una profundidad total de perforación de unos 13 m en la Zona 4.
- En los pozos de la red de control del complejo aluvial pleistoceno (UCB), se perforó al menos entre 6 y 10 metros en los materiales de marisma según las zonas para atravesar el complejo

superior. Esto supone una profundidad total de perforación aproximada de unos 18-27 m en la Zona 4.

Tabla 9: Información sobre el perfil en los puntos de muestreo

Zona	Sondeo	Tipo de material, espesores expresados en m					Espesor arcillas Gibraltor
		Espesor Rellenos	Espesor UFS	Espesor UA	Espesor UFI	Espesor UCB	
4	P44	13,5	14,7	---	---	4,8	
	P45	11,5	5,5				
	P46	10,5	4,5				
	P47	11	13	1	---	10,25	2,75
	P48	10,9	4,1				
	P49	11,35	12,65	---	---	4,3	
	P50	10	5				
	P51	9,7	7,8	3,3	---	5,2	
	P52	9,5	5,5

	P60	11,2	3,8				
	P61	5,2	13,4	---	---	8,4	
	P62	8,8	5,8				
	P63	5,6	3,6				
	P64	7,75	9,15	---	---	5,1	

Nota: en rojo los espesores obtenidos se corresponden con el fin de sondeo, por lo tanto, no son valores del espesor completo del paquete.

La media de los espesores de materiales de relleno en la Zona 4, es de 9.6 m, teniendo una distribución más homogénea en su espesor que la Zona 1. Los mayores valores se localizan en el punto P44, 13.5 m y los de menor potencia en el entorno de la zona más al noreste: P61, P63, P62 y P64.

El espesor medio del complejo estuarino superior y medio (UFS, UA y UFI) en la Zona 4 es de 10.9 m, aunque la presencia de la unidad arenosa (UA) es insignificante en esta zona, reducida a un par de puntos en las proximidades del caño de Mendaña (P47 y P51).

Los materiales de estuario van engrosando su potencia hacia el Río Tinto.

Finalmente, la unidad conglomerática basal (UCB), aparece como un paquete que buza hacia el Río Tinto. Los valores medios de espesor están próximos a 9.5 m.

7. Instalación de piezómetros

En principio, los piezómetros se dividieron en 3 redes diferentes, según la profundidad de ubicación del ranurado:

- Red de control de las aguas contenidas en los rellenos (fosfoyesos, cenizas, inertizado, RSU, etc. según los casos), para caracterizar aguas presentes en los diferentes materiales de relleno.
- Red de control de las aguas contenidas en el complejo estuarino superior y medio (UFS, UA y UFI), para evaluar la calidad del agua en terreno natural inmediatamente inferior al nivel de rellenos, para evaluar la transferencia de contaminantes desde el nivel superior.
- Red de control de las aguas contenidas en aluvial pleistoceno del complejo estuarino inferior (UCB), en este caso para estudiar las aguas en el nivel correspondiente al acuífero inferior con cierta permeabilidad y continuidad.

Características Sondeos

G. ANÁLISIS PIEZOMÉTRICO

1. Sistemas de circulación

El análisis piezométrico se efectuó partiendo del análisis individualizado de las 3 redes contempladas.

Tabla 14: Lecturas relativas y cota absoluta resultante del nivel piezométrico en bajamar en los pozos instalados en Zona 4

Piezómetro	Fecha	Hora	Profundidad NP desde boca piezómetro (m)	Z boca piezómetro (m)	Cota absoluta NP (msnm)	Paquete geológico	Litología en el ranurado del piezómetro

Tabla 2: Resumen de piezometría por materiales y estado de la marea

			NP mínimo (msnm)	NP máximo (msnm)	NP medio (msnm)
ZONA 4	Bajamar	Rellenos	4.27	7.26	5.76
		UFS	4.37	6.07	5.49
		UCB	0.89	1.39	1.09
	Pleamar	Rellenos	4.28	7.26	5.76
		UFS	4.38	6.12	5.51
		UCB	1.12	1.51	1.34

A través del estudio de los datos obtenidos en cada nivel hidrogeológico investigado, la relación entre los mismos y su relación con la cota topográfica de los materiales geológicos identificados, se diferenciaron dos sistemas de circulación de aguas:

- Acuitardo superficial con nivel freático libre, constituido por el complejo estuarino superior y medio (UFS, UA y UFI) y los rellenos antrópicos, materiales fundamentalmente limosos y con similar permeabilidad en la Zona 4.
- Acuífero profundo semiconfinado, de nivel piezométrico inferior al paquete anterior, constituido por la UCB (en la Zona 4).

Tabla 3: Resumen de piezometría por sistemas de circulación y estado de la marea

			NP mínimo (msnm)	NP máximo (msnm)	NP medio (msnm)	Δh entre sistemas (m)
ZONA 4	Bajamar	Rellenos+UFS	4.271	7.259	5.642	4.55
		UCB	0.886	1.389	1.091	
	Pleamar	Rellenos+UFS	4.276	7.264	5.653	4.43
		UCB	1.118	1.512	1.342	

Un primer grupo de valores oscila aproximadamente entre 4.3 y 7.3 m en la Zona 4, sin apenas diferencias entre la pleamar y la bajamar, y están asociados a piezómetros instalados tanto en nivel de rellenos como de la UFS infrayacente.

Un segundo conjunto de datos, de cotas inferiores a los anteriores, oscila entre 1 y 1.5 m en la Zona 4, con diferencias entre la pleamar y la bajamar, y están asociados a piezómetros instalados en la UCB.

2. Direcciones de flujo y gradientes hidráulicos

En la Zona 4 la superficie freática libre describiría un montículo alargado, similar al relieve topográfico, donde la zona más elevada seguiría más o menos un eje longitudinal N-S que se curvaría hacia el W en sus tramos inicial y final, y que funcionaría como divisoria de aguas, dirigiéndose el flujo subterráneo perpendicularmente hacia los bordes de contacto con la Ribera de la Nicoba y el Río Tinto al E y S, y la Marisma de Mendaña al W, con gradientes hidráulicos que oscilarían entre el 2% y el 4%, sin advertirse apenas diferencias entre la pleamar y la bajamar.

La superficie piezométrica del acuífero semiconfinado en la Zona 4 parecería describir una pendiente muy suave en sentido general NE-E durante la bajamar, con un gradiente hidráulico del 0.1%, que se invierte completamente hacia el W y S durante la pleamar, con gradiente del 0.06% en este caso. No se podrían precisar muchos más datos acerca de su comportamiento, debido al reducido número de piezómetros disponibles en esta zona.

En este caso, no existirían aportes laterales importantes desde los materiales pliocuaternarios de Huelva, ya que hacia el N y W de la Zona 4 aflorarían son las margas azules del Tortoniense-Andaluciense, que constituirían un borde impermeable.

3. Influencia mareal

En la Zona 4 las variaciones importantes de nivel se producen en piezómetros instalados en el acuífero profundo de la UCB. No obstante, existen un par de piezómetros instalados en rellenos (P45) y en UFS (P46), situados ambos en la parte sur del emplazamiento, que muestran ciertas variaciones del nivel freático a causa del ciclo mareal.

Las variaciones en esta zona parecen graduarse desde las zonas más limítrofes con el río Tinto (P44, P47 y P49), hacia el interior del emplazamiento (P57).

La influencia mareal por tanto, está íntimamente ligada a la permeabilidad del material y a su proximidad al cauce del río Tinto, no existiendo una buena comunicación de la ría con los materiales de rellenos y la UFS (a excepción quizás del sur de la zona 4), o al menos no lo suficientemente fluida como para que sea advertida en el intervalo de tiempo que abarca un semiperiodo mareal. Esto es acorde con la reducida permeabilidad de estos materiales y su clasificación como acuitardos.

Tabla 5: Influencia mareal observada en piezómetros de la zona 4

POZO	SUBZONA	NIVEL ACUÍFERO	NP somero (m)	NP profundo (m)	NP medio (m)	Amplitud observada (cm)	Efecto mareal
P49	Sector I	UCB	8,63	9,27	8,95	64	SI
P44	Sector I	UCB	11,06	11,68	11,37	62	SI
P47	Sector I	UCB	9,66	10,27	9,97	61	SI
P55	Sector I	UCB	8,17	8,66	8,42	49	SI
P51	Sector I	UCB	8,54	8,74	8,64	20	SI
P57	Sector I	UCB	8,80	8,99	8,90	19	SI
P46	Sector I	UFS	4,47	4,52	4,50	5	Escaso
P45	Sector I	RELLENOS	5,52	5,55	5,54	3	Escaso
P48	Sector I	RELLENOS	4,73	4,73	4,73	0	No
P50	Sector I	UFS	4,56	4,56	4,56	0	No
P52	Sector I	UFS	3,84	3,84	3,84	0	No
P53	Sector I	RELLENOS	3,18	3,18	3,18	0	No
P54	Sector I	RELLENOS	6,18	6,18	6,18	0	No

Cabe señalar que para efectuar el análisis piezométrico se efectuaron únicamente 2 mediciones del nivel de agua en los sondeos, correspondientes a sendos periodos de pleamar y bajamar (cada grupo de mediciones procuró efectuarse en el menor lapso de tiempo posible), posiblemente en el mismo día.

Se echa en falta el registro y análisis de series de medidas piezométricas a lo largo de un periodo de tiempo.

No se comparan las oscilaciones piezométricas observadas con el recorrido de la marea en la ría o en los caños principales, ni hasta que cota son inundados los materiales de relleno durante la pleamar. De esta forma, no se contempla la eventual entrada y salida periódica de agua de la ría hacia el interior de la Zona 4 a través de los caños de marea de menor rango que han sido fosilizados bajo los rellenos antrópicos.

Tampoco se contextualiza el momento en que se efectuaron las medidas piezométricas desde el punto de vista de la variabilidad estacional e interanual, e incluso mareal de rango más amplio que el diario.

Por tanto, algunas de las conclusiones que se desprenden del análisis piezométrico podrían ser cuestionables por parciales e incompletas

H. CONDUCTIVIDAD HIDRÁULICA

Con objeto de evaluar la conductividad hidráulica (vulgarmente permeabilidad) (sic) de los materiales presentes en el emplazamiento y su uso posterior en el análisis de riesgos, se llevaron a cabo diferentes pruebas in situ y de laboratorio.

- Ensayos de permeabilidad en cola en laboratorio, a partir de muestras inalteradas.
- Ensayos puntuales de permeabilidad in situ (Lefranc)
- Ensayos de recuperación tras el desarrollo de los piezómetros
- Ensayos de bombeo y recuperación en pozo de bombeo y satélites durante 24 h

1. Ensayos de permeabilidad en laboratorio

Para la determinación de la permeabilidad vertical en laboratorio se realizaron ensayos triaxiales de permeabilidad en cola sobre muestras inalteradas de terreno.

Tabla 12: Resultados ensayos de permeabilidad de laboratorio

Mediana	5,56E-08	5,56E-10	4,80E-05
Mínimo	2,08E-08	2,08E-10	1,80E-05

Entre los resultados obtenidos, ya se consideraba no obstante que los correspondientes a las litologías teóricamente más permeables (Cobertera vegetal, UA y UCB), con presencia de arenas y/o gravas, pudieran no ser totalmente representativos de los niveles litológicos caracterizados, por un posible sesgo en la selección de muestras.

En general, se considera que los resultados de las determinaciones de permeabilidad en laboratorio son muy poco representativas de la permeabilidad efectiva de los materiales a escala de emplazamiento.

2. Pruebas puntuales de permeabilidad in situ (ensayos Lefranc)

Durante las perforaciones de los sondeos mecánicos, se realizaron igualmente 9 ensayos puntuales de permeabilidad in situ del terreno, tipo Lefranc, a diferentes intervalos de profundidad.

Tabla 20: Resultados de ensayos in situ puntuales de permeabilidad (Lefranc)

Punto	Intervalo prof (m)	Litología	Método carga	Permeabilidad		
				cm/s	m/s	m/día
P47	36,7-38,0	Arcilla Gibrleón	Variable	2.26E-06	2.26E-08	1.96E-03
P55	33,0 - 34,0	Arcilla Gibrleón	Variable	6.18E-06	6.18E-08	5.34E-03
P47	7,1 - 8,4	Fosfoyeso	Variable	7.03E-06	7.03E-08	6.08E-03
P49	4,5 - 5,5	Fosfoyeso	Constante	6.78E-03	6.78E-05	5.85E+00
P64	4,5 - 6,3	Fosfoyeso	Constante	3.29E-03	3.29E-05	2.84E+00

P45	16,0 - 17,0	UFS	Variable	3.99E-07	3.99E-09	3.45E-04
P49	12,4 - 13,4	UFS	Variable	4.71E-07	4.71E-09	4.07E-04
P64	10,3 - 10,9	UFS	Variable	6.50E-07	6.50E-09	5.62E-04

Sintetizando los valores obtenidos en las zonas 1 y 4 para cada nivel litológico (salvo para UCB, para el que sólo se dispone de un dato), se obtienen los siguientes resultados.

Tabla 21: Resultados ensayos de permeabilidad lefranc para fosfoyesos

	Permeabilidad		
	cm/s	m/s	m/día
Máximo	6.78E-03	6.78E-05	5.85E+00
Promedio	2.02E-03	2.02E-05	1.74E+00
Mediana	1.35E-05	1.35E-07	1.16E-02
Mínimo	7.03E-06	7.03E-08	6.08E-03

Tabla 22: Resultados ensayos de permeabilidad lefranc para UFS

	Permeabilidad		
	cm/s	m/s	m/día
Máximo	3.40E-05	3.40E-07	2.94E-02
Promedio	8.12E-06	8.12E-08	7.02E-03
Mediana	1.76E-06	1.76E-08	1.52E-03
Mínimo	3.99E-07	3.99E-09	3.45E-04

Tabla 23: Resultados ensayos de permeabilidad lefranc para Arcillas de Gibrleón

	Permeabilidad		
	cm/s	m/s	m/día
Máximo	1.17E-05	1.17E-07	1.01E-02
Promedio	5.05E-06	5.05E-08	4.36E-03
Mediana	4.22E-06	4.22E-08	3.65E-03
Mínimo	6.10E-09	6.10E-11	5.27E-06

Se considera que los ensayos de permeabilidad in situ pueden no ser representativos de la permeabilidad de los materiales a escala de emplazamiento, aunque muchas veces, y sobre todo para materiales poco permeables en los que no puede plantearse un ensayo de bombeo, pueden ser el único dato disponible.

3. Ensayos de recuperación en el desarrollo de los piezómetros

En la Zona 4 se realizaron 4 ensayos de este tipo.

La mayoría de los supuestos que permiten aplicar este método se cumplirían a la escala a la que se realizan los ensayos, salvo el requisito de que los pozos sean totalmente penetrantes en el acuífero.

Tabla 24: Resultados de ensayos de recuperación (método de Jacob) en el desarrollo de piezómetros

Punto	Material en zona saturada	Coeficiente correlación	Ordenada en el origen (b)	Transmisividad T (m ² /día)	Permeabilidad K			Ratio t/t ₀ (>10%)	Ratio b/s _{max} (<50%)	(t+t ₀)/t cuando s=0 (<5)
					cm/s	m/s	m/día			
P48	RELLENOS (fosfoyesos y RCD)	0,997	0,145	0,29	4,35E-05	4,35E-07	3,76E-02	37%	4%

Aunque se considera que los ensayos de recuperación en el desarrollo de los piezómetros son más representativos de las condiciones hidráulicas s.l. de los materiales de un emplazamiento, la interpretación de sus resultados para derivar la permeabilidad correspondiente puede ser demasiado arbitraria.

4. Ensayos de bombeo y recuperación en pozo de bombeo y satélites durante 24 h

Se procedió a realizar un ensayo de bombeo de 24 horas de duración en la UCB de la zona 4, disponiendo pozo de bombeo central y piezómetros satélites de observación, con objeto de caracterizar de la forma más precisa posible la conductividad hidráulica del principal paquete acuífero del emplazamiento.

Se eligió finalmente el emplazamiento del sondeo P47 en la Zona 4, situado en el centro de la misma.

Según la testificación, en la UCB atravesada por el sondeo P47 dominaban las gravas y arenas con menor contenido de finos.

Se construyó un pozo central destinado al bombeo, con un diámetro de perforación de 320 mm y tubería de hierro de 250 mm de diámetro, con ancho de ranurado de 1.5 mm de puentecillo. A distancias aproximadas de éste pozo central de 10, 20 ó 30 y 50 m, se dispusieron piezómetros satélite de iguales características constructivas a las empleadas en la inspección de suelos, esto es, diámetros de perforación de 101mm y tubería de U-PVC de 60 mm de diámetro con ancho de ranurado de 0.5 mm.

TABLA 2. Profundidad de los reconocimientos

Denominación	Tipo	Profundidad (m)
PB-29	Pozo de bombeo	30.00
PB-47	Pozo de bombeo	38.10
PZ-29-1	Piezómetro	30.00
PZ-29.2	Piezómetro	30.00
PZ-29.3	Piezómetro	30.00
PZ-47.1	Piezómetro	38.10
PZ-47-2	Piezómetro	38.10
PZ-47.3	Piezómetro	38.10

El pozo de bombeo y los satélites se ubicaron y alinearon de tal forma que los piezómetros realizados en la primera etapa de la investigación fueron aprovechados como piezómetros satélites en estos ensayos de bombeo.

El ensayo de bombeo consistió en el bombeo de un caudal constante de 6 l/s durante 24h, y las lecturas de los descensos del nivel piezométrico tanto en el pozo central de bombeo como en los satélites a intervalos de tiempo cada vez mayores, hasta un intervalo máximo de 60 min.

Una vez parado el bombeo, se siguieron midiendo los descensos del piezométrico en el pozo central y los satélites para la evaluación adicional de la permeabilidad por el método de recuperación.

TABLA 4. Características de los pozos y piezómetros

Denominación	Tipo	Tramos ciegos		Tramos ranurados		Tipo tubería	Tapón de fondo	Grava de filtro (mm)	Tramos cementados	
		De	a	De	a				De	a
PB-2(P-47)	Pozo de bombeo	0,00	26,0	-	-	Hierro 4mm	si		0,00	26,00
		-	-	26,0	34,0	Hierro con puentecillo 1,5mm				
		34,0	35,0	-	-	Hierro 4mm	si	2mm/4mm	34,0	35,0
PZ-47.1	Piezómetro	0,00	26,0			PVC-4mm			0,0	26,0
				26,0	35,0	PVC RANURADO 0,5mm	si	2mm/4mm	-	-
PZ-47.2	Piezómetro	0,00	26,0			PVC-4mm			0,0	26,0
				26,0	35,0	PVC RANURADO 0,5mm	si	2mm/4mm	-	-
PZ-47.3	Piezómetro	0,00	26,0			PVC-4mm			0,0	26,0
				26,0	35,0	PVC RANURADO 0,5mm	si	2mm/4mm		

En el punto P47 las lecturas obtenidas registraron una importante influencia mareal, lo que obligó a considerar una serie de datos más reducida, correspondientes a un semiperiodo de marea. La evaluación de la recuperación en este pozo tampoco pudo llevarse a cabo por el mismo motivo.

Tabla 31: Resultados ensayo de bombeo 24h en P47 (Método de Theis)

Punto	Coeficiente de almacenamiento	Transmisividad T (m ² /día)	Permeabilidad K		
			cm/s	m/s	m/día
PB-2(P-47)	29,6	2,14	3,43E-03	3,43E-05	2,96
PZ-47.1	32,5	0,224	3,76E-03	3,76E-05	3,25
PZ-47.2	42,9	3,22E-07	4,97E-03	4,97E-05	4,29
PZ-47.3	51,1	4,71E-08	5,91E-03	5,91E-05	5,11

Tomando en consideración todos los valores obtenidos para la UCB en los 2 ensayos de bombeo efectuados en las zonas 1 y 4, se obtendrían los siguientes resultados:

Tabla 32: Resultados globales obtenidos en los ensayos de bombeo-recuperación

	Coeficiente de almacenamiento	Transmisividad T (m ² /día)	Permeabilidad K		
			cm/s	m/s	m/día
Máximo	88,7	2,14E+00	8,56E-03	8,56E-05	7,4
Promedio	61,9	2,99E-01	6,22E-03	6,22E-05	5,4
Mediana	67,0	1,27E-04	6,49E-03	6,49E-05	5,6
Mínimo	29,6	4,71E-08	3,43E-03	3,43E-05	3,0

La influencia mareal en el desarrollo del ensayo de bombeo en el pozo P-47 invalida la interpretación de este ensayo.

En el ensayo del pozo P-29, correspondiente a los mismos materiales UCB en la Zona 1, la interpretación efectuada parece cuestionable.

5. Resumen de resultados

En la siguiente tabla se sintetizan los resultados de permeabilidad obtenidos en las pruebas de las zonas 1 y 4 para cada litología, y se indican los valores más verosímiles o de mayor confianza que, según la calidad de las distintas fuentes, se propusieron para cada caso.

Datos dudosos. Probable sesgo en la selección de muestras tallables

Un único dato

Se consideró que la permeabilidad horizontal es normalmente mayor que la vertical en los materiales sedimentarios, ya que los materiales granulares se depositan con los ejes mayores paralelos a la horizontal, determinando una comunicación preferencial de los huecos en esta dirección.

El coeficiente de anisotropía, definido como la ratio entre las permeabilidades horizontal y vertical, sería máximo (65 aprox.) en la UFS, siendo menor en las arcillas de Gibrleón y en los fosfoyesos.

No se considera que los materiales presentes en la Zona 4 se encuentren bien caracterizados hidráulicamente a partir de las pruebas y ensayos de permeabilidad realizados.

Cualitativamente se consideraría más correcto lo siguiente:

$$K_{UCB} > K_{rellenos} > K_{UFS}$$

y

$$K_h \gg K_v$$

Como referencia, en la caracterización de la Zona 2,

$$K_{niveles\ de\ gravas\ profundos} = 1E-03\ m/s > K_{fosfoyesos} = 5E-7\ m/s > K_{marisma} = 1E-9\ m/s$$

y

$$K_h = 10\ K_v$$

I. CARACTERIZACIÓN HIDROGEOLOGÍA DEL EMPLAZAMIENTO

Los terrenos donde se ubica el emplazamiento en estudio no constituirían, en líneas generales, formaciones de una elevada permeabilidad, además de estar incluidos dentro del Dominio Público Marítimo-Terrestre, y por tanto, sujetos a elevadas concentraciones de sales, que hacen inviable o desaconsejable su utilización para diversos usos (agrícola, etc.).

A escala local del emplazamiento (zonas 1 y 4, en conjunto), y en base a las pruebas de permeabilidad y las medidas de niveles piezométricos, se diferenciaron dos paquetes litológicos de diferente permeabilidad y comportamiento hidrodinámico:

- Un primer paquete lo constituirían los rellenos antrópicos (fosfoyesos, cenizas, basuras, RCD, etc.), junto con la UFS infrayacente. Ambos tipos de materiales presentan, en líneas generales, permeabilidades horizontales de un orden de magnitud de $4.0E-07$ m/s, presentan una clasificación granulométrica muy similar (limos), y las medidas piezométricas realizadas en ambos niveles son coherentes unas con otras. Formarían un conjunto que se podría catalogar como acuitardo, con capacidad para almacenar agua, y transferirla con dificultad.
- Un segundo paquete lo constituirían las litologías más permeables; materiales de estuario con presencia de arenas (UA) más los limos arenosos y arenas y gravas fluviales de la UCB, interrumpidas según las zonas por la UFI (Zona 1 y, muy localmente, Zona 4), que no obstante no parece que tenga el espesor y la continuidad espacial suficientes para aislar hidrodinámicamente ambos niveles. Estos materiales poseen permeabilidades entre $1E-05$ y $7E-05$ m/s, niveles piezométricos coherentes, y constituirían un acuífero semiconfinado por los materiales acuitardos superiores.

J. DATOS BÁSICOS DEL FUNCIONAMIENTO HIDROGEOLÓGICO

Con los datos hidrogeológicos obtenidos, fundamentalmente permeabilidades y piezometría, se realizó una "estimación grosera" (sic) del balance y el funcionamiento hidrogeológico del emplazamiento.

Como se ha explicado en apartados anteriores, la sucesión de materiales en la Zona 4, con las permeabilidades resultantes obtenidas, y en función de las lecturas de piezometría en esos niveles, determinaría la existencia de un paquete superior constituido por rellenos y UFS, que funcionaría como un acuitardo, alimentado básicamente por la infiltración de agua de lluvia, con una superficie piezométrica libre o superficie freática, a una cota topográfica situada en torno a la mitad del espesor del paquete de rellenos antrópicos, que drenaría lateralmente a favor de los límites topográficos de la zona en dirección a los cursos de aguas superficiales, y también en profundidad, hacia otro paquete inferior más permeable, de comportamiento acuífero, constituido en la Zona 4 prácticamente en exclusiva por la UCB.

Este paquete permeable profundo, formado por UCB, emparedado entre la UFS y las arcillas de Gibrleón, posee una superficie piezométrica de cota superior al techo de la unidad, y similar o ligeramente superior al techo de la UFS o muro de los rellenos, dentro del paquete superior. Es decir, que estaría saturado de agua en la totalidad de su espesor, y acumularía agua a presión, con una superficie ideal o teórica de equilibrio con la presión atmosférica acorde más o menos con la superficie topográfica original de la marisma. Recibiría los aportes del paquete acuitardo superior, más aportes laterales por el este, procedentes del agua de mar en momentos de pleamar, como parece desprenderse de la influencia mareal observada en los pozos de esta unidad en la Zona 4, donde se llega a invertir el sentido del flujo hacia el oeste en esos instantes de pleamar.

En los apartados sucesivos, se tratará de evaluar de la forma más aproximada posible la importancia relativa de estos flujos, que determinarán el funcionamiento global de la unidad:

- Drenaje lateral de los paquetes acuitardos y acuíferos hacia los cursos superficiales o subsuperficiales.
- Drenaje en profundidad del acuitardo al acuífero.
- Recarga del paquete acuitardo y congruencia de la misma con sus drenajes.
- Reservas de los paquetes acuitardo y acuífero y relación con los drenajes.

Se considera que el esquema de funcionamiento hidrogeológico es incorrecto, por las siguientes razones:

- En función de las características hidráulicas más plausibles (aunque teóricas) de los materiales del emplazamiento, parece que debería considerarse la existencia, de techo a muro de las siguientes unidades hidroestratigráficas:
 - Acuífero libre superior, formado por los rellenos antrópicos; a la base, canales mareales cubiertos por los rellenos, por los que se canaliza la entrada y salida subterránea del agua del apilamiento antrópico.
 - Acuitardo intermedio, constituido por UFS.
 - Acuífero confinado inferior, constituido por UCB, conectado con el mar a cierta distancia de la costa.
- Desde el punto de vista del balance hídrico, no se tiene en cuenta una posible desaturación de los fosfoyesos vertidos, que habría estado desarrollándose a lo largo de un extenso periodo de tiempo, y que tendría como consecuencia una deriva piezométrica negativa en los rellenos.

1. Descargas laterales

De acuerdo con la ley de Darcy, el caudal del flujo subterráneo por un medio poroso queda determinado por la siguiente relación:

$$Q_h = K_h B l_1 \frac{\Delta h}{l_2}$$

Donde:

Q_h: Caudal horizontal circulante por el material granular

K_h: Permeabilidad horizontal del material granular

B: Potencia o espesor del material poroso.

l₁: Longitud del material granular en dirección perpendicular al flujo. Multiplicada por la potencia anterior, determinaría la superficie o sección perpendicular al flujo.

Δh: Diferencia de potencial hidráulico entre el punto de partida y el final considerados.

l₂: Longitud de material atravesado por el flujo considerado, en la dirección del máximo gradiente hidráulico.

Datos de partida para el material acuitardo

La dificultad del cálculo de los caudales laterales en el material acuitardo, reside en que el flujo es radial en varias direcciones hacia los límites del emplazamiento desde unos puntos de mayor cota, y no lineal en una única dirección como en la ley de Darcy.

Se optó por calcular caudales lineales parciales en varias direcciones representativas de los diferentes gradientes hidráulicos existentes, y por considerar como sección transversal al flujo, representativa del conjunto, aquella configurada por el recorrido o perímetro de alguna curva isopieza intermedia entre los puntos de mayor y menor cota, multiplicado por el espesor saturado medio del paquete acuitado.

Tabla 35: Espesores medios saturados de los rellenos en zonas 1 y 4 y comparación con espesores totales. Comparación profundidad nivel piezométrico del acuífero inferior y espesor de los rellenos

	Espesor rellenos (m)	Profundidad media nivel freático (m)	Espesor rellenos saturados (m)	Ratio espesor saturado/total	Profundidad media nivel piezométrico acuífero inferior (m)
Zona 1	4.90	2.68	2.22	45%	4
Zona 4	9.60	4.78	4.82	50%	9.6

Tabla 37: Permeabilidad horizontal ponderada para el paquete acuitado en zona 4

	k_i (m/s)	b_i (m)	$k_i \cdot b_i$ (m ² /s)	b (m)	K_h (m/s)
Rellenos	4.35E-07	4.8	2.10E-06	15.8	4.13E-07
UFS	4.04E-07	11.0	4.44E-06		

Datos de partida para el acuífero inferior

Para la zona 4, ya que el sentido del flujo se ve fuertemente influenciado por el ciclo mareal, se calculó un caudal circulante para la bajamar y otro para la pleamar, empleando en el caso de la bajamar el Δh existente en bajamar entre los puntos P51 ó P52 y P47, y en pleamar el existente entre P49 y un punto situado entre P47 y P45, tomando como distancia (l_1) las longitudes entre los puntos antes citados.

Para la permeabilidad horizontal del acuífero inferior en la zona 4, donde sólo está presente la UCB, se tomó el dato medio existente (6.22E-05 m/s) para este material en los ensayos de bombeo-recuperación de 24 h, tomando todos los datos disponibles (ensayos en P29 y P47).

Descarga lateral media en el material acuitado

Tabla 40: Descarga lateral estimada en el acuitado en zona 4

K_h (m/s)	B (m)	l_1 (m)	Δh (m)	l_2 (m)	Gradiente $\Delta h / l_2$	Q_h (m ³ /día)	Q_h (m ³ /día)
4.13E-07	15.8	2633	5.0	250	2.0%	30	48
			5.0	112	4.5%	66	

Estas descargas se producirían de forma más o menos radial hacia el borde perimetral de cada zona, hacia los caños de marea por el límite norte de la marisma y desde éstos hacia el Río Tinto, y por la parte central de la marisma directamente hacia el Río Tinto.

Descarga lateral media en el acuífero inferior

Tabla 43: Caudal lateral circulante por el acuífero inferior en zona 4

Marea	K_h (m/s)	B (m)	l_1 (m)	Δh (m)	l_2 (m)	Gradiente $\Delta h / l_2$	Q_h (m ³ /día)	Q_h (m ³ /día)
Pleamar	6.22E-05	9.2	700	0.3	496	0.06%	21	34
Bajamar			1100	0.4	460	0.09%	47	

(?)

No sería previsible que este caudal pase directamente al interior del curso superficial del Río Tinto, a menos que desapareciese o se adelgazase la UFS en algunas zonas lo suficiente para que existiera comunicación ente ambas masas de agua. Lo más normal sería que estas descargas sigan un flujo neto en profundidad hacia la parte distal del estuario y el mar.

El sentido del flujo sería influenciado por el estado de la marea, cambiando entre la pleamar y bajamar, no dirigiéndose por tanto de forma nítida hacia el centro de la cuenca. (?)

Se trata de un cálculo teórico del caudal de las descargas, sin posible contraste con medidas reales, partiendo de un esquema de flujo inadecuado y considerando datos piezométricos y de permeabilidad cuestionables.

2. Caudal de rezume desde el acuitado al acuífero

La importancia de este aporte desde el material acuitado al acuífero, quedaría determinada por lo que se conoce como coeficiente de percolación o percolamiento, que se define como el caudal de agua que fluye a través de la unidad de superficie del límite entre el acuífero y el acuitado semiconfinante, cuando la diferencia entre los niveles de ambas unidades es la unidad:

$$Lc = \frac{k'}{b'}$$

Donde:

k' : Conductividad hidráulica vertical del estrato semiconfinante

b' : Espesor (saturado) del estrato semiconfinante

Tabla 46: Permeabilidad vertical (k') y coeficiente de percolación (Lc) del paquete acuitado en Zona 4

	k_i (m/s)	b_i (m)	b_i/k_i (s)	b (m)	K' (m/s)	Lc (s^{-1})
Rellenos	1,02E-07	4,82	4,73E+07	15.82	8.65E-09	5.47E-10
UFS	6,17E-09	11	1,78E+09			

Para comprender mejor la magnitud de este aporte por percolación al acuífero inferior, y compararlo con el caudal horizontal circulante por este último (ya calculado en el apartado anterior), se hizo una primera estimación del caudal aportado en la base del acuitado confinante a través de la Ley de Darcy, que para un flujo vertical, quedaría:

$$Q_v = K_v A \frac{\Delta h}{b}$$

Donde:

Q_v : Caudal vertical en la base del material semiconfinante

K_v : Permeabilidad vertical del material semiconfinante

A': Superficie perpendicular al flujo. Sería el área cubierta por las zonas 1 y la zona 4 estudiada (Sector I).

Δh : Diferencia de potencial hidráulico entre la superficie freática del acuitardo superior y la superficie piezométrica del acuífero semiconfinado.

b: Longitud de material atravesado por el flujo considerado, en este caso, sería el espesor saturado del material semiconfinante.

Tabla 47: Caudales de rezume desde el acuitardo hacia el acuífero en Zonas 1 y 4

	Kv (m/s)	A (Ha)	Δh (m)	b (m)	Gradiente $\Delta h / b$	Qv (m3/día)
Zona 1	9.47E-09	365	2.22	6.32	35%	1048
Zona 4	8.65E-09	75	4.43	15.82	28%	157

(?)

Si se compara este aporte por goteo o rezume vertical con el caudal circulante por el acuífero inferior calculado en el apartado anterior, en cantidades anuales, obtenemos los siguientes resultados:

Tabla 48: Comparación caudales verticales de rezume y caudales laterales en acuíferos de las Zonas 1 y 4

	Qv acuitardo (m3/año)	Qh acuífero (m3/año)	Ratio Qh acuífero/Qv acuitardo
Zona 1	382.612	36.521	10%
Zona 4	57.284	12.449	22%

(?)

Se trata de un cálculo teórico del caudal de percolación, sin posible contraste con medidas reales, partiendo de un esquema de flujo inadecuado y considerando datos piezométricos y de permeabilidad cuestionables.

3. Salidas conjuntas del sistema acuitardo

Otra comparación interesante sería la de los caudales laterales y verticales en el material acuitardo, así como su cuantificación unitaria, que arroja los siguientes resultados:

Tabla 50: Síntesis y comparación de descargas verticales y laterales en acuitardos de las Zonas 1 y 4

	Qh (m³/año)	Qv (m³/año)	Qtotal (m³/año)	Ratio Qh/Qv
Zona 1	879	382612	383492	0,2%
Zona 4	17.548	57284	74832	30,6%

(?)

Se considera que estos valores son muy chocante, teniendo en cuenta que previamente se había establecido que, en la UFS, $k_h/k_v=65$.

4. Recarga

Teniendo en cuenta los drenajes laterales y en profundidad (rezume) calculados anteriormente para el paquete acuitardo, si comparamos los resultados obtenidos para la recarga de este paquete, obtendríamos los siguientes porcentajes:

Tabla 71: Ratio entre estimaciones de recargas por infiltración de lluvia y drenajes de salida en el sistema acuitado

		P0=33mm	P0=47mm	P0=69mm	P0=96mm
RAU 75	Zona 1	84%	103%	116%	123%
	Zona 4	89%	108%	123%	130%
RAU 100	Zona 1	61%	79%	93%	99%
	Zona 4	64%	83%	98%	105%

Se observa que en gran parte de las combinaciones posibles (en rayado), los resultados obtenidos para las recargas son congruentes con las salidas, teniendo en cuenta la incertidumbre de las magnitudes de entrada, y que las salidas se han evaluado someramente en base a una única campaña de piezometría, realizada en un año de especial pluviosidad (un 60% por encima de la media).

Se trata de un contraste de valores sin validez, puesto que se comparan los resultados de un cálculo de la recarga muy teórico con unos drenajes de salida también cuestionables.

5. Reservas

Tabla 72: Intervalos y valores adoptados de porosidad eficaz (%)

	Fosfoyeso	UFS / UFI	UA	UCB
Intervalo	6-19	1-15	9-30	5-41
Media	10	6	21	30

Tabla 73: Estimación de reservas en el acuitado y comparación con drenajes laterales y verticales anuales

	Superficie (ha)	Espesor saturado (m)	Reservas (m3)	Ratio Qh/Res	Ratio Qv/Res
Zona 1	365	6,32	1.834.509	0,05%	21%
Zona 4	75	15,82	943.578	1,9%	6%

Tabla 74: Estimación de reservas en el acuífero profundo por saturación

	Superficie (ha)	Espesor saturado (m)	hi	me	Reservas por saturación (m ³)
Zona 1	365	22,7	UA	7,7	0,21
			UFI	5,5	0,06
			UCB	9,5	0,30
Zona 4	75	9,2	-	-	0,30
					2.093.000

Tabla 75: Estimación de reservas en el acuífero profundo por almacenamiento elástico

	Sup (ha)	Altura NP (m)	S	Reserva (m3)
Zona 1	365	27,7		422473
Zona 4	75	20,1	4,18E-03	63072

Tabla 76: Estimación de reservas totales en el acuífero profundo y comparación con drenaje lateral de este acuífero y rezume recibido del acuitado superior

	Reserva saturada (m3)	Reserva elástica (m3)	Total Reservas (m3)	Ratio saturado/total	Ratio elastico/total	Ratio Qh/Res	Ratio Qv/Res
Zona 1	17.444.866	422473	17.867.339	98%	2%	0,2%	2,1%
Zona 4	2.093.000	63072	2.156.072	97%	3%	0,6%	2,7%

Se considera que los valores de porosidad eficaz utilizados para el cálculo son, en buen medida, arbitrarios y poco justificados, al proceder de análisis granulométricos que tiene poca relación con la porosidad eficaz "in situ" de los materiales del emplazamiento.

K. CONCLUSIONES DE LA CARACTERIZACIÓN HIDROGEOLÓGICA

Hidrodinámicamente se advierten dos sistemas de circulación de aguas subterráneas:

- *Acuitardo superior, formado en la Zona 4 por rellenos antrópicos y la UFS, UA (de escasa representación) y UFI, que funciona como acuífero libre, con nivel freático situado como término medio a media altura de los rellenos.*
- *Acuífero semiconfinado inferior, formado por la UCB. El nivel piezométrico se sitúa a la altura, o ligeramente por encima, del techo de la UFS (nivel de la marisma original), y en cualquier caso es inferior al nivel freático del acuitardo superior.*

El paquete acuitardo superior se recarga fundamentalmente por las precipitaciones, y drena con una dirección de flujo radial hacia el perímetro de la Zona 4, es decir, hacia la marisma y el curso del río Tinto, así como verticalmente en profundidad, hacia el acuífero inferior (rezume).

A pesar de poseer este paquete acuitardo una permeabilidad horizontal media, ponderada en base a los espesores de rellenos y UFS, muy superior ($4.1E-07$ m/s) a la vertical (de $9.47E-09$ a $8.65E-09$ m/s), las descargas laterales son cuantitativamente menos importantes que las verticales, debido fundamentalmente a la elevada superficie de contacto por la que se produce el rezume vertical. (?)

- *El drenaje lateral anual se cuantifica en unos 18400 m³/año totales (para ambas zonas), entre un 0.06 y un 2.2% de sus reservas estimadas, y supone aproximadamente un 1% del caudal que circula por el curso continental del río Tinto (medido 30 km río arriba y sin tener en cuenta las corrientes mareales del estuario) en los momentos más desfavorables (estiaje), siendo inferior al 0.05% respecto a su caudal medio. Este drenaje lateral resulta ser un 0.2% del vertical en zona 1 y algo más relevante, un 30.6% en la zona 4.*
- *El rezume vertical anual total se cuantifica en unos 440.000 m³/año, lo que supone del 6 al 21% de las reservas estimadas del acuitardo para zona 4 y zona 1 respectivamente.*

El acuífero semiconfinado inferior recibe el rezume del acuitardo superior, así como en la zona 1, aportes laterales subterráneos de los materiales acuíferos plio-cuaternarios de Huelva, y drena en dirección SE en profundidad (bajo la UFS) hacia el centro del estuario. Sufre una importante influencia mareal por su mayor permeabilidad, que en momentos de pleamar, provoca que el flujo se estanque (zona 1) o incluso se invierta (zona 4).

Este efecto de taponamiento parcial que ejerce la marea, provoca que el caudal en el acuífero inferior, que es inferior al 1% de sus reservas, sea considerablemente inferior al caudal del rezume que le llega verticalmente desde el acuitardo (un 10-22% el primero respecto al segundo), tendiéndose a acumular el agua a presión, y provocando una elevación generalizada del nivel piezométrico en la zona, fundamentalmente en zona 1, donde este nivel se eleva 1 m sobre el nivel original de la marisma. (?)

Se considera que la caracterización geológica del emplazamiento pueda ser posiblemente razonable, pero la caracterización hidrogeológica, el esquema de funcionamiento de las aguas subterráneas y el balance hídrico son inasumibles.

2.2. Reconocimiento de campo

Se ha comprobado la localización y el estado de las perforaciones efectuadas en investigaciones anteriores, con el objeto de identificar aquellas que puedan ser susceptibles de utilización para la determinación de niveles piezométricos, la instalación de registradores automáticos de nivel y otros parámetros o la realización de pruebas de permeabilidad o ensayos de bombeo.

En la siguiente figura se muestra el emplazamiento de la totalidad de los sondeos efectuados durante los trabajos de egmasa en la Zona 4, resaltándose los que han podido ser localizados en la actualidad

Figura 1. Perforaciones ejecutadas por egmasa en la investigación previa (en naranja, perforaciones localizadas en la actualidad)

2.3. Ubicación, diseño y construcción de nuevos sondeos de reconocimiento y piezométricos

Los objetivos de los 6 pares de sondeos de reconocimiento con testigo continuo que se han ejecutado son los siguientes:

- Reconocimiento de la columna estratigráfica objeto de estudio en su totalidad, es decir, tanto el apilamiento de fosfoyesos como los materiales de marisma infrayacentes hasta alcanzar las margas azules que constituyen el límite impermeable inferior del sistema de flujo subterráneo.
- Realización de pruebas para la determinación de la permeabilidad en avance durante la ejecución de los sondeos, con objeto de realizar una caracterización hidráulica inicial de los materiales atravesados. Dado el tipo de materiales atravesados, las pruebas han sido de tipo Lefranc y Gilg-Gavard de carga variable.
- Instalación como piezómetros para la determinación del nivel de agua en su interior

En la siguiente figura se muestra el emplazamiento de los sondeos ejecutados.

Figura 2. Emplazamiento de los sondeos de reconocimiento ejecutados durante el presente estudio

Además de estos sondeos de reconocimiento, se ejecutaron dos pozos de mayor diámetro con el objetivo de realizar ensayos de bombeo.

Estos pozos denominados SH-2 y SH-5, se construyeron próximos a los pares de sondeos piezométricos S-2, S-2B y S-5, S-5B, para utilizar estos últimos como piezómetros de observación a la hora de realizar los ensayos de bombeo.

En la figura siguiente se muestra la localización de los pozos de bombeo.

Figura 3. Emplazamiento de los pozos de bombeo

Los pozos se ejecutaron con la Sonda de la empresa Perforaciones Jiennenses MARCHAL S.L.

Maquina F.D.O. 400 con capacidad de tiro de 20 toneladas montada sobre camión 4x4. Compresor de 25 bares INGERSOLL-RAND de 1170 y ATLAS COPCO de 25 bares.

Las características de los pozos construidos, los materiales atravesados y el diseño de entubación con tubería de PVC de 144 x 8 mm se encuentran recogidas en las siguientes figuras.

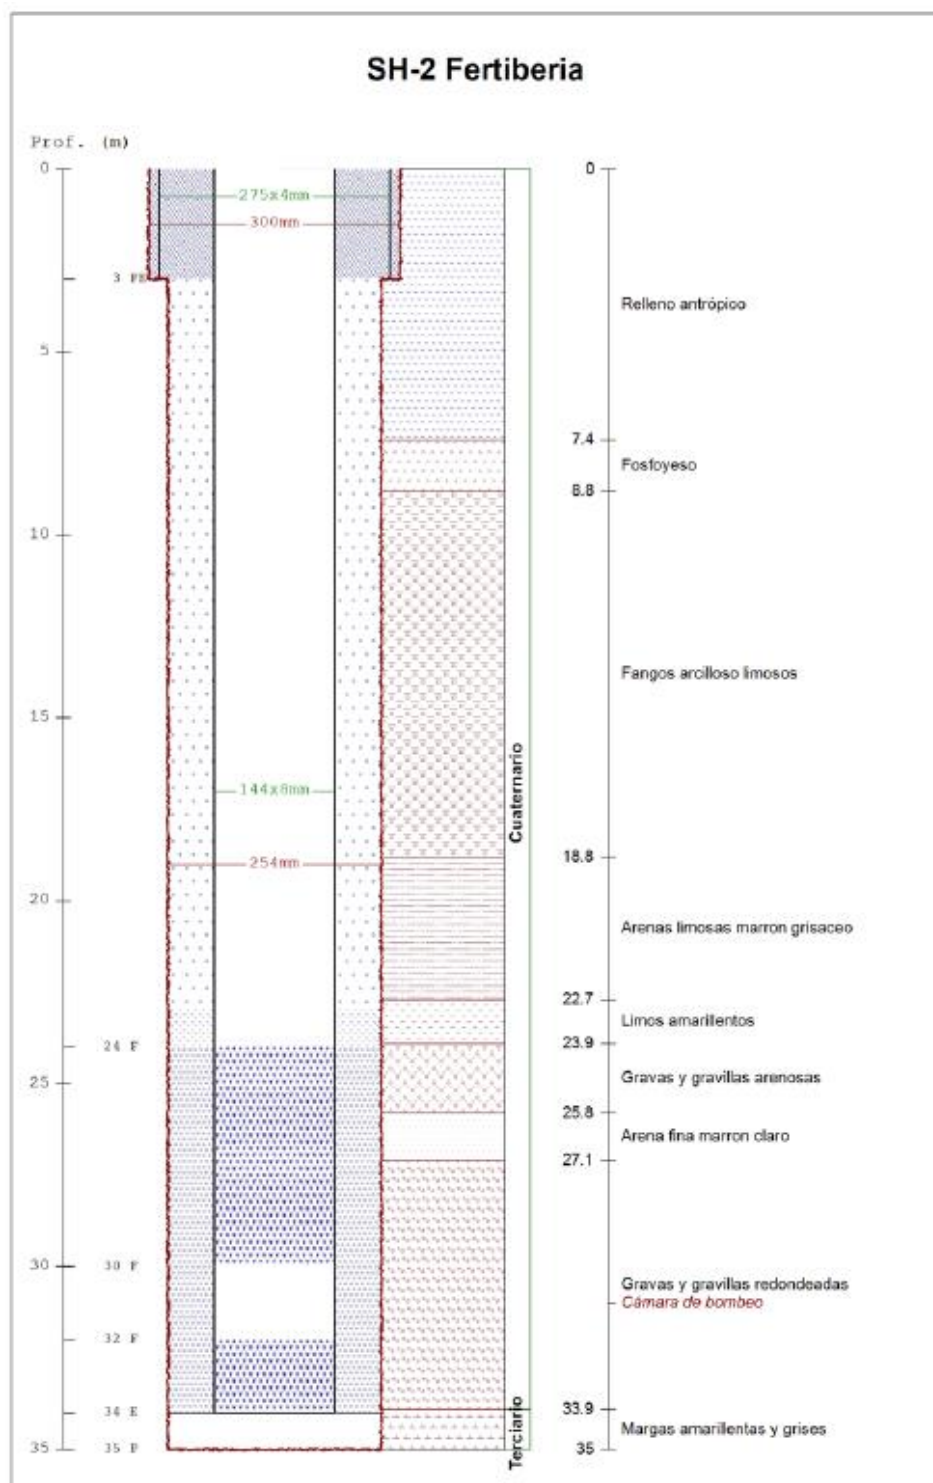

Figura 4. Croquis del pozo de bombeo SH-2

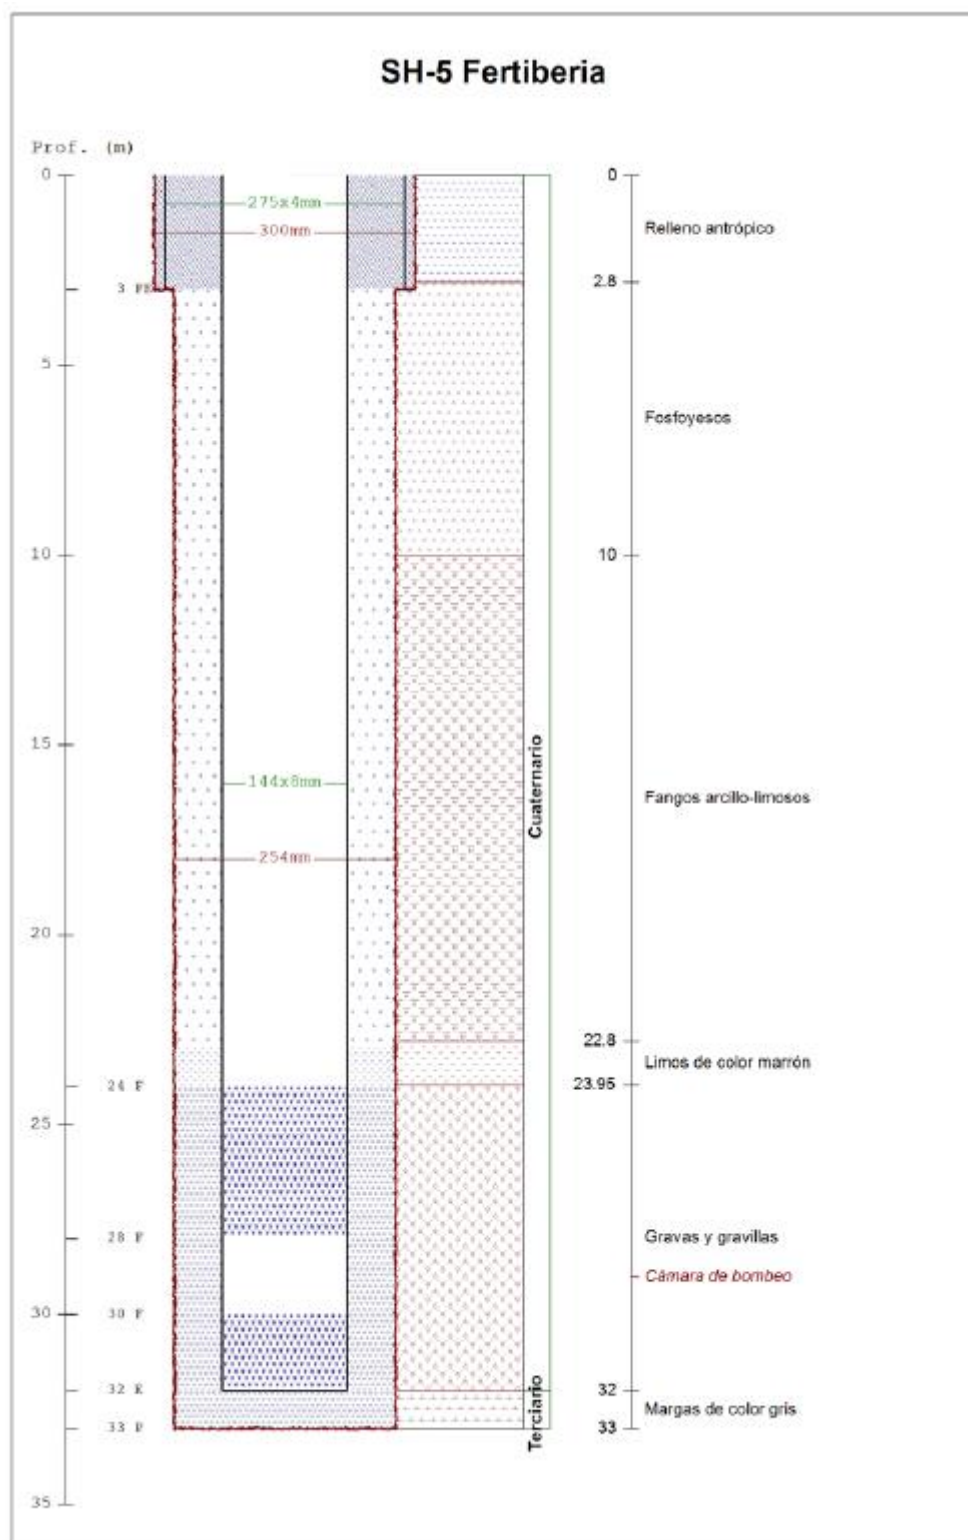

Figura 5. Croquis del pozo de bombeo SH-5

2.4. Ensayos de bombeo

El método más representativo para la obtención de parámetros hidráulicos de un acuífero es el ensayo de bombeo, en el cual se efectúa la extracción de un caudal de agua durante un espacio de tiempo significativo y se observan las variaciones en la profundidad del nivel del agua producidas en el propio pozo de bombeo y otras perforaciones cercanas disponibles, tanto durante el descenso de los niveles producido por la extracción de agua como en la recuperación de los mismos tras la conclusión del bombeo.

Los ensayos de bombeo constituyen, indudablemente, el método más extendido y de mejor aplicación y mayor garantía en sus resultados, usado tradicionalmente al objeto de establecer las características hidráulicas de los acuíferos, así como el grado de perfección del acabado de los pozos.

La interpretación de los datos obtenidos en los ensayos de bombeo se realiza mediante los métodos más adecuados a cada caso (Jacob, Theis, Hantush, etc.) y utilizando herramientas informáticas estándar o software especializado, de forma a que en el caso de un ensayo estándar se podría obtener la siguiente información:

- eficiencia del pozo
- curva característica
- transmisividad
- permeabilidad
- porosidad eficaz / coeficiente de almacenamiento (en el caso de disponer de piezómetros)
- radio de influencia
- caudal de explotación óptimo

El objetivo de los ensayos de bombeo efectuados ha sido la obtención de los parámetros hidráulicos de los materiales de la Zona 4 de las balsas de depósito de los fosfoyesos para caracterizarlos hidrogeológicamente.

Los parámetros hidráulicos que caracterizan un acuífero y que son necesarios para la modelización numérica del flujo del agua subterránea en su interior son los siguientes:

- Transmisividad
- Permeabilidad
- Coeficiente de almacenamiento
- Porosidad eficaz

Básicamente, las pruebas de bombeo han consistido en la extracción de agua desde los pozos SH-2 y SH-5 con diferentes caudales y la observación de las variaciones en la profundidad del nivel del agua producidas en los propios pozos de bombeo y en varias perforaciones cercanas que se han utilizado como piezómetros de observación, tanto durante el descenso de los niveles como en la recuperación de los mismos tras la conclusión de los bombeos.

En la figura siguiente se muestra la localización de los pozos de bombeo y los sondeos piezométricos de observación utilizados para los ensayos.

Figura 6. Emplazamiento de los pozos en los que se ha efectuado ensayos de bombeo y los piezómetros de observación

Los ensayos de bombeo se realizaron con un equipo de la empresa BOINS, S.L compuesto por un grupo FIAT ALFO 250KVA 400CV, alternador Mecc Alte, tubería de impulsión con diámetro interior de 50 mm, bomba sumergible de 4", marca SATURN, modelo EFL20 de 7.5 CV de potencia. El caudal se controló mediante aforadores de 6" y 2" con tubo pitot calibrado y diafragmas de 3", 2" y 1".

Para el control continuo del nivel de agua tanto en los pozos de bombeo como en los sondeos piezométricos de observación se utilizaron equipos compactos de sensor-registrador tipo CeraDiver y CTDiver marca WATER.SLB de Schlumberger con un rango de medida de 0 a 10 m y rango de conductividad de 120.000 mS/cm, programados para efectuar lecturas cada minuto. Durante la

realización del ensayo, el control instantáneo del nivel del agua se efectuó mediante medidas de la profundidad del agua desde la superficie utilizando una sonda manual graduada en centímetros.

En los cuadros adjuntos se indican los sondeos piezométricos de control en ambos ensayos de bombeo y en Anejo 1, se recogen los datos de los ensayos de bombeo.

2.5. Seguimiento hidrogeológico de la infraestructura de control

La red de control piezométrico de la Zona 4 se encuentra constituida por:

- Los sondeos de reconocimiento ejecutados durante el presente estudio.
- Los pozos de bombeo
- Las perforaciones correspondientes a la investigación previa que han podido ser localizados
- La ría

La situación de la totalidad de perforaciones operativas que constituyen la red de control piezométrico se muestran en la siguiente figura.

Figura 7. Red de control piezométrico

Con fecha 1 de julio de 2021 quedaron instalados con sensor-registrador tipo CeraDiver y CTDiver los sondeos recogidos en el cuadro adjunto, con toma de datos con periodicidad horaria.

3. Caracterización hidrogeológica

3.1. Geología del emplazamiento

La superficie sobre la que comenzaron a verterse los fosfoyesos estaba constituida en su mayor parte por materiales fangosos, cubiertos por la vegetación de bajo porte típica de estos ambientes, y surcada por canales de marea o pequeños esteros de anchura métrica por los que se producía el principal trasiego del agua del estuario entre la bajamar y la marea alta. Estos canales conforman una red dendrítica con canales principales, afluentes y subafluentes. Desde este punto de vista, los principales canales mareales de las marismas de los ríos Tinto y Odiel son los propios ríos.

Dentro de los depósitos de marisma, los canales mareales constituyen elementos lineales de alta energía relativa respecto a las zonas simplemente inundadas. En las zonas de baja energía se depositan los materiales detríticos más finos (arcillas y limos) junto con materia orgánica, generando los fangos típicos de marisma, mientras que el fondo de los canales mareales es ocupado por los materiales más gruesos (arenas y gravas).

Foto 1. Marisma actual

De una forma simplificada, los depósitos de marisma relacionados con el emplazamiento constituyen un prisma sedimentario de edad holocena constituido por el apilamiento de los materiales detríticos correspondientes a las sucesivas disposiciones de canales de marea y llanuras de inundación que han tenido lugar a lo largo del tiempo geológico. Bajo el apilamiento de los fosfoyesos este prisma sedimentario alcanza un espesor comprendido entre los 25 y 30 m, apoyándose en un nivel de conglomerados pleistocenos y estos, a su vez, sobre la formación denominada "margas azules" de edad pliocena.

Como consecuencia de la distribución superficial de los canales de marea respecto a la llanura de inundación, a la migración lateral de los mismos dentro de una dinámica fluvio-mareal y a los diferentes episodios transgresivos y regresivos que ha sufrido el nivel del mar a lo largo del tiempo, una sección vertical de los depósitos de marisma presenta un predominio de materiales fangosos y arcillosos salpicado por lentejones de arenas y gravas, más o menos extensos e interconectados, correspondientes a los paleocanales. Se comprende que la identificación, cartografía y correlación exacta de los diferentes depósitos de los paleocanales presentes bajo el emplazamiento es prácticamente imposible con la información de que se dispone, procedente, en su mayor parte, de unos cuantos sondeos de reconocimiento.

3.2. Identificación y caracterización de unidades hidroestratigráficas

En los estudios hidrogeológicos que llevan aparejados la realización de una modelización numérica de flujo es conveniente emplear para la caracterización de los materiales el concepto de unidad hidroestratigráfica (UH), en el sentido de considerar de una forma sintética unidades geológicas con propiedades hidráulicas similares, que además presentan comportamientos diferenciados desde el punto de vista del sistema de flujo: varias formaciones geológicas pueden ser unidas para constituir una unidad hidroestratigráfica, y una formación geológica puede ser dividida en acuíferos y unidades confinantes.

Para establecer el modelo conceptual de funcionamiento hidrogeológico del apilamiento de los fosfoyesos y su entorno es necesario definir, como mínimo, las siguientes unidades hidroestratigráficas:

UH Fosfoyesos-Rellenos

La estructura interna del apilamiento de los fosfoyesos es muy compleja, consecuencia de los procesos a que han sido sometidos a lo largo del tiempo. Originalmente, la decantación de la pasta líquida procedente de la factoría debió producir una sedimentación subhorizontal de sucesivas capas de fosfoyeso. Esta sencilla estructura debe estar presente en la mayor parte del volumen del apilamiento, pero se han producido procesos y actividades que la han modificado, tales como:

- compactación de las capas profundas de yeso a medida que crecía la altura del apilamiento
- movilización de fosfoyesos secos para la construcción de diques, caballones, terraplenes y el tendido de taludes.

Esta desestructuración de las capas horizontales de yesos, aunque afectan a un volumen relativamente reducido del apilamiento en su conjunto, pueden tener importancia desde el punto de vista hidrogeológico en cuanto al esquema de circulación de las aguas embebidas en los fosfoyesos. La imposibilidad de establecer la estructura interna real del apilamiento justifica la simplificación de

considerar el conjunto de fosfoyesos como una unidad hidroestratigráfica caracterizada por un único conjunto de parámetros hidrogeológicos.

UH Marisma

Esta unidad hidroestratigráfica está constituida por todos los materiales prácticamente impermeables presentes en los depósitos de marisma sobre los que se apoya el apilamiento. Se incluyen, por tanto, los fangos, arcillas y limos arcillosos correspondientes a las llanuras de inundación del prisma sedimentario holoceno, que constituyen la mayor parte del mismo.

No se dispone de datos empíricos sobre el valor de la permeabilidad de esta unidad, aunque por comparación con los datos correspondientes a otras unidades hidroestratigráficas y tras comprobación con la modelización numérica de flujo efectuada en la Zona 2, se considera representativa de esta unidad una permeabilidad horizontal (k_h) de $1E-09$ m/s y una permeabilidad vertical (k_v) unas 10 veces menor, es decir $1E-10$ m/s.

UH Niveles de gravas profundas

Está constituida por un par de niveles de gravas y conglomerados, que corresponden a depósitos de carácter fundamentalmente fluvial, el más profundo de los cuales es de edad pleistocena y se emplaza, para toda la extensión del emplazamiento, bajo el prisma sedimentario de la marisma y por encima de las margas azules impermeables. El otro nivel se emplaza intercalado en la UH Marisma y no se extiende bajo la totalidad del emplazamiento.

3.3. Hidroquímica

3.3.1. Introducción

Los residuos de la producción de ácido fosfórico mediante el ataque de roca fosfatada con ácido sulfúrico y agua son fosfoyeso y una fracción residual de ácidos procedentes del proceso industrial, principalmente ácido fosfórico, aunque también sulfúrico y fluorhídrico, además de agua.

Estos residuos de la producción, en forma de pasta líquida, se vertieron durante décadas sobre una marisma. El vertido se realizó inicialmente de forma directa sobre la marisma. La decantación de esta pasta produce la separación del residuo sólido que constituye el fosfoyeso y el líquido denominado agua de proceso. Con el fosfoyeso se levantaron posteriormente diques que delimitaron recintos en los que se producía la decantación del residuo y el almacenamiento o evaporación del agua precipitada sobre estas balsas.

El fosfoyeso sólido constituye un residuo industrial, en principio, inerte, aunque contiene impurezas metálicas procedentes de la roca fosfatada, además de trazas de uranio y torio.

Por su parte, el agua de proceso embebido en los fosfoyesos presenta un carácter extremadamente ácido, que moviliza los contaminantes contenidos en los mismos.

Desde que se dejaron de producir los vertidos no hay incremento en la cantidad de ácido presente en el apilamiento de fosfoyesos. El único líquido que se incorpora al apilamiento por su superficie es una fracción del agua de lluvia que se precipita sobre el mismo.

3.4. Modelo conceptual de funcionamiento hidrogeológico

Desde un punto de vista general, el emplazamiento de los fosfoyesos se comportaría como un acuífero multicapa subhorizontal, en el que los niveles permeables (el propio apilamiento de los fosfoyesos y los residuos vertidos sobre ellos funcionando como nivel libre, y los diferentes niveles de arenas y gravas de la marisma y las gravas de base pleistocenas como acuíferos confinados) se encuentran separados por materiales poco permeables que actúan como acuitardo (los fangos y arcillas de la marisma).

En estas circunstancias, el flujo de agua entre los niveles permeables a través del acuitardo será muy reducido, aunque no nulo al no ser la permeabilidad de los fangos y de las arcillas igual a cero. Este flujo se establecería desde los niveles permeables que tienen un mayor nivel piezométrico (los fosfoyesos) hacia los niveles detríticos de la marisma.

El modelo conceptual de funcionamiento hidrogeológico en la situación actual es el siguiente:

- La recarga de los fosfoyesos y resto de vertidis se produce por la infiltración de una parte de las precipitaciones sobre su superficie. Esta infiltración es directa e inmediata sobre las superficies horizontales de los fosfoyesos, y muy reducida sobre sus taludes.
- El agua infiltrada desde la superficie alcanza en poco tiempo la superficie de saturación de los fosfoyesos, que se encuentra relativamente cerca de la superficie.
- El agua contenida en los poros de los fosfoyesos corresponde mayoritariamente a agua de proceso, caracterizada por su elevada acidez y contenido iónico, lo que le confiere una densidad superior a la del agua dulce e incluso a la del agua del mar.
- La descarga "natural" del agua contenida en el apilamiento se producirá por el perímetro del vertido, en el contacto entre los fosfoyesos y la marisma.
- De esta forma, el esquema general de circulación del agua de los fosfoyesos se produce, de forma radial y centrífuga, desde las zonas de recarga centrales y elevadas hacia el perímetro del apilamiento.
- La naturaleza prácticamente impermeable de las arcillas y los fangos de marisma que ocupan la mayor parte de la superficie del contacto bajo los fosfoyesos provocará que el agua drenada

por los mismos se canalice a través de los canales de marisma directamente enterrados por el vertido de los fosfoyesos, generando las denominadas "salidas perimetrales".

- A pesar de la muy baja permeabilidad de los fangos y arcillas de la marisma, este parámetro no puede considerarse igual a cero. Por tanto, debe considerarse la existencia de un flujo desde los fosfoyesos hacia los depósitos de marisma. La magnitud de este flujo de agua será directamente proporcional a la permeabilidad que se adopte para los fangos y las arcillas, pero significativamente inferior al correspondiente a las salidas perimetrales.
- Los canales arenosos presentes en los depósitos de marisma y las gravas actuarán como colectores del agua subterránea que se filtra a estos depósitos desde los fosfoyesos, debido a su permeabilidad varios órdenes de magnitud respecto a los fangos y arcillas. La mayor parte de estas filtraciones se canaliza, lógicamente, a través de los niveles arenosos superiores, los más cercanos al vertido.
- La circulación del agua a través de los paleocanales está regida, de una parte, por la influencia mareal, cuyo nivel oscila en torno a la cota media del nivel del mar y, de otra, de la transmisión del nivel piezométrico correspondiente al apilamiento de los fosfoyesos. El efecto combinado de estas acciones es un flujo de ida y vuelta en su interior pero con una resultante neta final de flujo hacia el estuario o el mar.
